

Research Artifact Preservation and Audio Publication Supplement

AI-Human Music Detection Thesis Project

13 September 2026: versioned delivery checkpoint

1 Scope and scientific status

This supplement records preservation work after the English thesis v7. It does not change feature definitions, model fits, thresholds, experimental memberships, or reported classification results. The BC extension, expanded YuE Native30 evaluations, locked scoring, legacy spectral comparison and Native60 transfer experiments are complete. Whole-project audio delivery is *not* complete. Publication status must not be substituted for scientific validation, and file counts must not be interpreted as independent songs.

Code and versioned catalogues are maintained in [the project GitHub repository](#). Audio is published in [the public HF dataset](#). The local report root, including older results, is `/Users/yi/Documents/report/music_ai_detection_20260912`.

2 Original-source and actual-input coverage are different

At the fixed HF revision `caed9220f68b258e9c2dcb89792ccb1fe4d1dc61`, the public snapshot contained 16,795 direct audio/MIDI paths and 130,247,953,279 logical bytes. Archive members were not enumerated. Of 10,141 historical recorded raw hashes, 7,781 matched public audio objects and 2,360 did not. These counts exclude later-only identities and do not prove processed-input coverage.

A separate audit read the actual `audio_path` files named in the historical 10-second and 30-second metadata. All 14,246 distinct filesystem paths were readable. Their 14,638 experimental memberships resolve to 14,244 unique byte objects. Only 966 objects matched the pre-supplement public snapshot; 13,278 objects, totaling 19,083,227,708 bytes, did not. The larger 13,480 unmatched count from the initial audit refers to memberships, not unique files. Runtime crop settings are retained; the audit does not claim that every runtime crop was rendered or every separated stem was enumerated.

3 Independently accepted processed-input supplements

Supplement	File objects	Bytes
DiffRhythm pilot	100	410,987,527
Ishizaka/MusicNet subset	78	57,343,890
Historical MAESTRO	600	1,259,759,294
MagnaTagATune	500	218,959,824
Total	1,278	1,947,050,535

Each acceptance checks an exact public manifest and notice at one fixed revision and every remote file hash/size. It is not a full waveform redownload. DiffRhythm retains 50 outputs and ten conditioning groups; Ishizaka retains 39 source-reviewed recordings; MAESTRO retains 300 performances. These are processed versions of existing inputs.

The acceptance records reside under `current_results/` in folders `hf_diffrrhythm_test_views_v1`, `hf_ishizaka_test_views_v1`, `hf_maestro_historical_views_v1`, and `hf_mtt_test_views_v1`. Each contains `INDEPENDENT_ACCEPTANCE.json` and `manifest.json`. The GitHub dataset catalogues preserve corresponding receipts and batch records.

4 Remaining processed-file backlog

After these acceptances, 12,000 objects (17,136,177,173 bytes) remain without final acceptance in the frozen audit scope. A dispatched publisher is not proof of a live transfer or completed release.

Checkpoint category	Objects
AIME: dispatched, not accepted	5,500
ACE-Step/HeartMuLa: dispatched, not accepted	800
FMA licensed candidates: dispatched, not accepted	316
Suno: prepared, not dispatched	900
FMA: no-derivatives restriction	390
FMA: unresolved or mixed terms	194
Other source rights/provenance unresolved	3,900

The FMA screening retains exact license versions and jurisdiction where recorded; it does not relicense all files under a single modern CC license. Metadata declarations are not a warranty of every underlying recording right. ND processing restrictions are handled conservatively. Other source issues include individual recording rights, creator attribution and explicit redistribution-consent requests. Preserved bytes are not equivalent to permission to publish them.

5 Upload recovery and reproducibility safeguards

Two distinct HF limits were observed: short-window API limits and a response stating 128 repository commits per hour. The latter terminated the AIME publisher after 1,900 processed files. Earlier short-cooldown recovery attempts for open-model and FMA files also returned 429 responses. Verified process identities were used when replacing those outdated recovery workers; existing audio, batch receipts and logs were preserved. Replacement workers wait 3,900 seconds before resuming and honor longer server retry delays. This checkpoint does not claim that the cooldown has ended or uploads have resumed.

Authentication is passed through standard input, not committed to the repository. Recovery uses per-output process locks. Completed batches are rechecked against remote hashes before being skipped; new files are checked against their expected local hashes before upload. These checks are separate from the final anonymous acceptance.

6 Code and analysis references

Current scripts are under the GitHub directory `current/yue2_500_extension_20260911/`. Relevant implementations are:

- `audit_historical_test_views_v1.py` and `plan_historical_test_view_objects_v1.py`: actual-input hashing and deduplication.
- `reconcile_processed_delivery_v1.py` and `classify_processed_backlog_v1.py`: receipt-bound coverage and backlog partitioning.
- `plan_fma_test_view_rights_v1.py`: conservative per-recording license screening.
- `resume_processed_upload_v1.py`: locked, rate-aware recovery.
- Source-specific `publish*_test_views_v1.py` and `verify*_test_views_v1.py`: publication and acceptance.

Analysis products are preserved under local `datasets/`: `historical_public_coverage_20260913_v2`, `historical_test_view_objects_v1`, `processed_delivery_reconciliation_v1`, `processed_backlog_v1`, and `fma_test_view_rights_v2`. Their COMMIT records bind output hashes and exact audit scopes.

Six upload-backoff tests and four license-screening tests passed locally. Byte comparisons found all 162 current YuE-extension Python scripts and all 392 current audio-phenomena Python scripts matched GitHub staging. A separate 1,223-file publication manifest records source hashes and zero matches for the checker’s literal credential patterns. Neither check constitutes a full security audit, complete environment capture, or all-project source coverage.

7 Outstanding work

Finish and independently accept remaining permitted uploads, dispatch the prepared Suno publication when quota allows, reconcile unenumerated stems and earlier/external scopes, resolve remaining source permissions, and update the final delivery index and thesis references without overwriting this checkpoint. No experimental result is changed by this supplement.
